

Low fidelity #1

Energy choice and child mortality relationship #2

#3

High fidelity: flower petal as energy source, center circle CO₂ emissions, outline thickness - child mortality

- Solar
- Wind
- hydro
- biofuel
- fossil.

Short Reflection: The aim of this visualization was to create an engaging glyph that ties energy mix directly to environmental and health outcomes. By representing each country as a flower, the petals encode the share of different energy sources, while the center size reflects CO₂ emissions and the center outline thickness represents child mortality. This design makes the link between energy choices and human impact visually intuitive.

In doing so, I deliberately broke conventional design rules: instead of using standard axes or bar charts, I mapped quantitative data onto a metaphorical object (flowers). I also used center size and outline thickness in a non-traditional way to encode emissions and mortality, prioritizing symbolism and aesthetics over strict perceptual accuracy.

The intended audience is non-technical stakeholders such as policymakers, NGOs, or the general public. The visualization is designed to be memorable and accessible, sparking reflection on how energy mix decisions affect both environmental sustainability and human health.
